

# MSP430 Programming Instructions

---

PMEL's Engineering Development Division uses MSP430 microcontrollers in many of the custom circuits. The following is the procedure for programming the microcontrollers, also known as "flashing".

## Requirements

The following are the basic hardware and software requirements for loading binary files onto the microcontroller.

### Hardware

- Texas Instruments MSP-FET Flash Emulation Tool
- EDD Custom 0.100" Pitch x14-pin to 0.050" pitch x10-pin converter

### Software

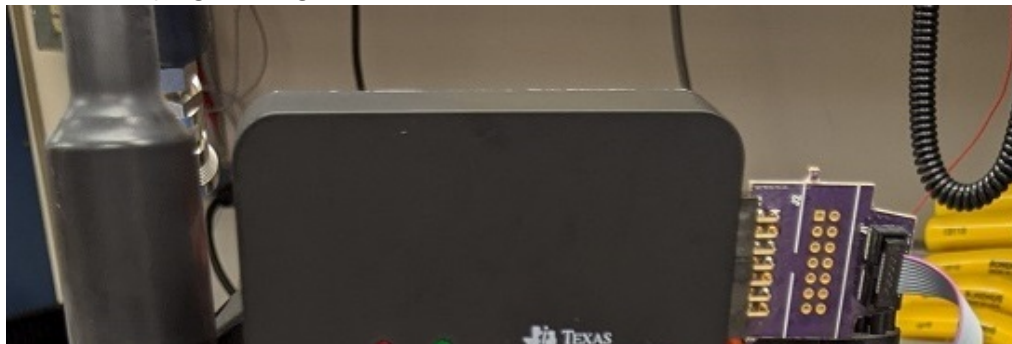

- Elprotronic, Inc. FET-Pro-430-LITE
  - Free download from [www.elprotronic.com](http://www.elprotronic.com)

### Files

- Pre-generated binary files for target device
  - File should have the form "DeviceName\_version.txt"

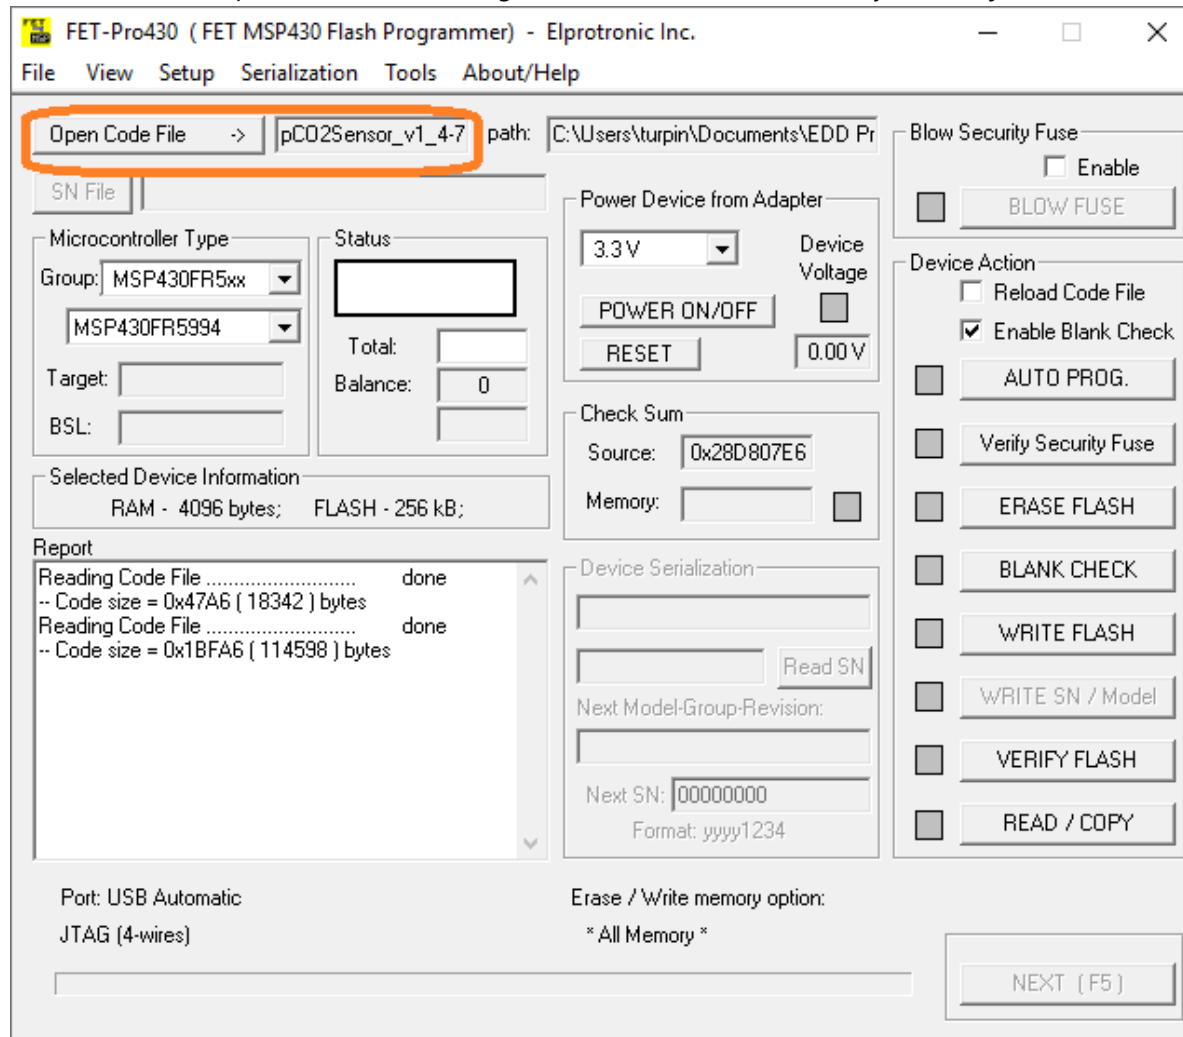

## Loading "Binary" files to target

1. Connect the programming cable to the microcontroller and the MSP-FET.

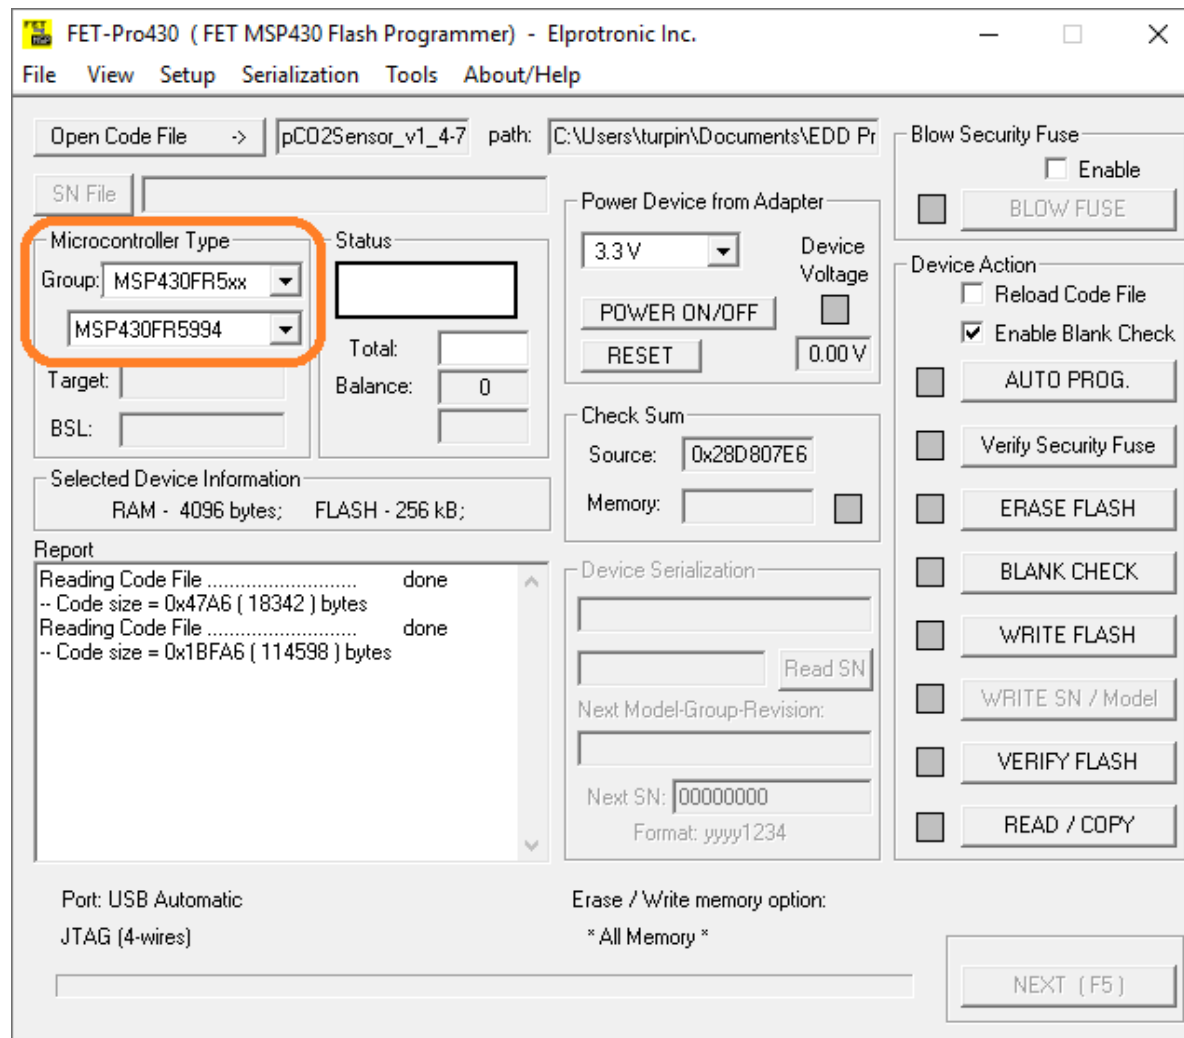

2. Apply Power to the target board
3. Open the FET-Pro-430 program
4. Press the button "Open Code File ->", navigate to the location of the "binary" file (ProjectName.txt)

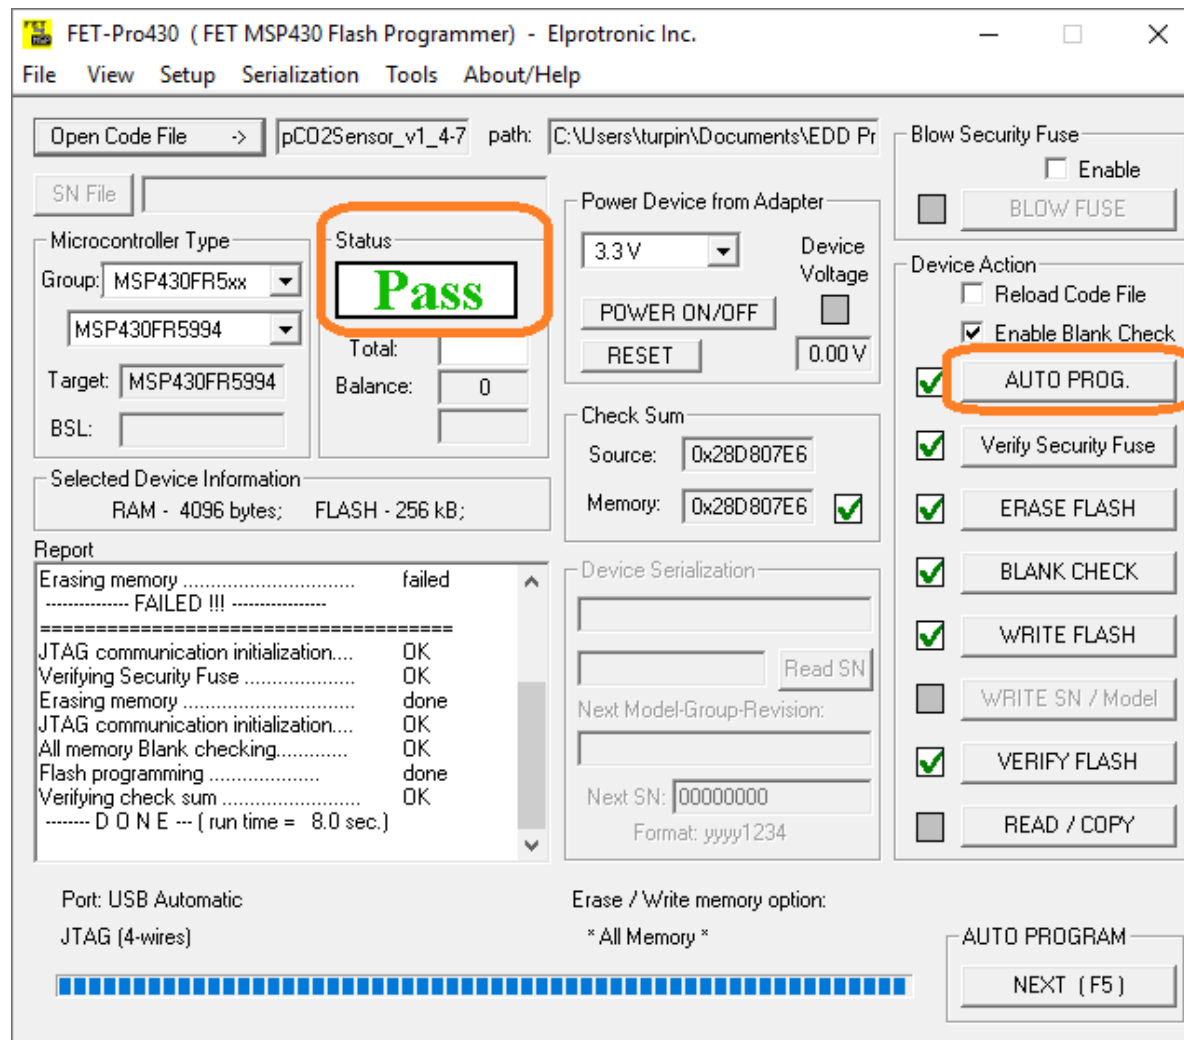

5. In the Microcontroller Type block (refer to User Manual for values)

- \* In "Group", select the general type of MSP430 used.
- \* On the next line, select the specific type of MSP430 used

1. In the "Device Action" block, press "AUTO PROG."

- \* If successfull, the "Status" block should show **\*\*\*Pass\*\*\***
- \* If unsuccessfull, press "ERASE FLASH" and try step 6 again.

1. The device is now programmed

**NOTE:** The board may require additional configuration settings over the console. Consult the User Manual for the corresponding device.
